### White Paper

## Critical Preoperative Assessment to Improve the Outcome of Cataract Surgery

### Xiaolin Gu<sup>1</sup>, MD, PhD Li Wang<sup>2</sup>, MD, PhD

 Alcon Medical Affairs, North America; Fort Worth, TX
Cullen Eye Institute, Department of Ophthalmology, Baylor College of Medicine

### **Key Take-Aways**

- Managing ocular surface diseases (OSD), especially dry-eye disease (DED), is critical to improve visual outcomes and patient satisfaction after cataract surgery. The ASCRS Cornea Clinical Committee recommended algorithm for preoperative diagnosis and treatment of OSD is available for adoption
- 2. Performing a spectral-domain or swept-source macular optical coherence tomography (OCT) on every single cataract patient preoperatively, and not just on premium intraocular lens (IOL) patients, may prevent "visual surprise"
- 3. Other preoperative steps to improve outcomes include: minimizing the biometry measurement error by ensuring "no touching, no drops" before measurement, selecting highly accurate and reproducible technology, keeping consistency in measurement and technology usage, understanding the limitation of technology and utilizing additional measurements when necessary, and implementing advancements in measurement technology

### Introduction

With the advancement in IOL technology, cataract surgery has evolved to have the similar patient expectations as a refractive procedure.<sup>1</sup> A larger proportion of the baby boomer generation, which has a greater awareness and knowledge of cataract surgery, is now in need of presbyopia correction with cataract surgery. Their visual outcome expectations, especially those who are willing to pay for premium IOLs, are much higher.<sup>2</sup>

This white paper will focus on the critical steps during preoperative assessment of cataract surgery that help surgeons to provide better visual outcomes and patient satisfaction.

### Ocular surface evaluation and Dry-eye Disease (DED) management

Ocular surface disease (OSD), most commonly DED, can reduce vision or visual quality and adversely affect biometric measurements before refractive corneal or cataract surgeries; all of which can lead to poor visual outcome and lower patient satisfaction.<sup>3</sup>

OSD is more common in aging population and is more prevalent in women.<sup>4</sup> Additionally, with environmental and lifestyle changes, such as the widespread usage of computers, tablets and digital phones, more patients are now affected by DED.<sup>5</sup> The DED incidence in cataract patients, especially asymptomatic patients, is now considered highly under-estimated.<sup>6</sup> Signs and symptoms of DED are also been shown to be poorly correlated and patient-reported symptoms alone cannot be used to accurately assess the ocular surface.<sup>7</sup> Trattler et al<sup>8</sup> reported in a prospective health assessment of cataract patients' ocular surface study (PHACO) that almost 60% of routine cataract patients were asymptomatic, but 63% patients had abnormal tear film breakup time and 77% had positive corneal staining. Gupta et al<sup>7</sup> showed that 80% of all studied cataract patients and 85% in the asymptomatic group had at least 1 abnormal tear test result (osmolarity or MMP-9) suggestive of ocular surface dysfunction.

American Academy of Ophthalmology and the Cornea ASCRS Clinical Committee have recommended preoperative evaluation, especially for refractive cataract surgeries, to comprehend all the aspects of potential deleterious effect on post-operative outcomes, including the ocular surface.<sup>3,9</sup> Recently, the ASCRS Cornea Clinical Committee published a consensus-based diagnostic OSD algorithm (Appendix 1) for efficiently diagnosing and treating visually significant OSD before refractive cataract or corneal refractive surgery, to improve postoperative visual outcomes and patient satisfaction.<sup>3</sup>

Any OSD that results in corneal staining or hyperosmolarity and/or irregular astigmatism is considered as visually significant OSD, which requires postponing surgery and commencing OSD treatment in

order to achieve accurate preoperative biometric measurement for accurate IOL power calculation in the case of cataract surgery to improve postoperative visual outcomes.

Based on the recommendation from ASCRS Cornea Clinical Committee<sup>3</sup> and TFOS DEWS II (Tear film & Ocular Surface Society Dry Eye WorkShop II)<sup>10</sup>, preoperative OSD screening includes:

- 1. OSD symptom investigation: For example, ASCRS SPEED II pre-operative questionnaire.
- 2. OSD signs investigation: combination of two simple objective noninvasive screening tests, which have been shown to help identify OSD in asymptomatic preoperative cataract patients.<sup>7</sup>

Test	Positive Sign for OSD
Tear Osmolarity (mOsm/L)	>307 in one eye or >7 inter-eye difference
MMP-9 (inflammatory marker)	≥40 ng/ml

- 3. Topography and Tomography: Koch and Wang<sup>11</sup> recently shared their preoperative assessment recommendations and emphasized the importance of including corneal topography and tomography. They found that: 1) placido ring topography is helpful to visualize and rule out corneal surface pathology, such as DED, epithelial basement membrane dystrophy and Salzmann's nodular degeneration (Figure 1); and 2) Tomography aids in ruling out corneal ectatic disease.
- 4. Clinical examination: lid, Meibomian gland, cornea/conjunctiva exam including cornea staining, fluorescein tear film breakup time test (TBUT) and Schirmer's test.
- Other optional objective OSD tests to help to establish OSD subtype and visual significance. Tests include meibograhy, non-invasive TBUT, ocular scatter index (OSI), aberrometry, lipid layer thickness (LLT), quantification of tear meniscus height measurement using anterior segment OCT or multipurpose corneal topographer.

Figure 1a. A case of dry eye showing irregularities on the corneal topography map and placido ring image.

Figure 1b. A case of epithelial basement membrane dystrophy treated with the epithelial debridement: before the epithelial debridement (left) and after epithelial debridement (right).

### **Macular OCT Scan**

Preoperative evaluation of the retina, especially at the macula region may help rule out the conditions that could limit overall visual outcome after cataract surgery, especially in those patients considering advanced technology IOLs. It also provides a valuable baseline to monitor patients who may develop problems postoperatively. Recent studies of routine OCT in preoperative evaluation found the rate of clinically undetectable macular disease ranged from 4.6% to 13.2%.<sup>12</sup> Performing an OCT scan of the retina is quick, safe and easy. Retinal specialist Dr. Steve Charles urges 1) performing an OCT on every single cataract patient preoperatively, not just premium IOL patients to help prevent "visual surprises"; 2) performing a spectral domain or swept source OCT; and 3) carefully reviewing multiple scan images, not just one image.<sup>13</sup>

# Preoperative biometry for accurate IOL power determination

In addition to excluding or managing any ocular pathology that may affect post-operative visual outcomes, a critical step to improve the refractive outcome is to avoid preoperative biometry error to ensure the input parameters (Table 1) for IOL power formulas are accurate. As Dr. Warren Hill stated, multiple components are involved in IOL power calculation, perfection of one individual component may not significantly affect the outcome in a series of patients. However, if one measurement is incorrect, for that individual patient, a refractive miss is guaranteed.<sup>14</sup>

Axial length (AL)

Horizontal white to white (HWTW)
Refraction

#### Table 1: Preoperative measurements for Cataract Surgery

Efforts to minimize the biometry error include:

- Standardizing biometry to ensure measurements are taken before any procedures that could alter the tear film or ocular surface, such as applying eye drops.<sup>15</sup> For contact lens users, measurements should be taken at least two weeks after discontinuing soft contact lens wear or one month without rigid gas permeable lens wear and followed by topography exam to confirm stabilization.<sup>3</sup> For visually significant OSD, biometry measurement should be repeated after OSD management.
- 2. Standardizing biometry technique and instrument use to ensure measurements are consistent and mostly operator independent. Noncontact optical biometry, such as LenSTAR LS900 (Haag-Streit), IOLMaster 700 (Zeiss) and ARGOS (Alcon), has become the gold-standard because of its ease of use, accuracy and reproducibility.
- 3. Understanding the limitation of the technologies, use additional measurements when data do not meet the validation criteria.

Ocular Optical biometers have excellent accuracy and reproducibility. However, some patients need additional measurements when the data fail the validation criteria set forth by the manufacturers (Appendix 2 and 3)<sup>16</sup> or based on personal experience. Many successful practices adopting a "preflight checklist" proposed by Dr. Hill, to incorporate those preoperative

measurement validation guidelines, either from industry or individually developed by each practice, is an excellent way to warrant additional investigations to avoid "refractive miss". The validation criteria guide users to obtain accurate keratometry and axial measurements. To apply the validation criteria, we recommend inspection of the following aspects:

a. **Quality of the reflected LED images:** to ensure accurate keratometry, it is required that the reflected LED images have good quality. A case example with irregular LED reflection using IOLMaster 700 (Zeiss) is shown in Figure 2a; repeated exam using LenSTAR 900 (Haag Streit) showed much better LED images in the same eye (Figure 2b) and a significant difference in astigmatism (Figure 2c).

#### Figure 2: Case example of importance on quality inspection of reflected LED images

a. Irregular LED reflection on IOLMaster 700 (Zeiss) (OS Astigmatism = 2.48 @ 3°).

#### b. Better quality of LED images on LenSTAR900 (Haag Streit)(OS Astigmatism = 0.88 @ 4°).

	Mean Ks	Astigmatism
IOLMaster 700	42.16 D	2.48 @ 3°
LenStar 900	41.91 D	0.88 @ 4°
Difference	0.25 D	1.60 D

c. Difference in measured keratometry and astigmatism.

- b. **Individual parameters:** the manufacturer's validation criteria (Appendix 2 & 3) list the reasonable range for several parameters, such as the average keratometry, anterior chamber depth (ACD), and lens thickness. For example, if a phakic ACD is >4.5 mm for either LenSTAR 900 (Haag-Streit) or IOLMaster, additional measurements are recommended.
- c. **Standard deviation (SD):** a smaller SD indicates more consistent repeated measurements. If the SD is greater than the criterion, inspection of raw data should be performed, outlier data should be deleted, or additional exams should be added. Figure 3 is an example to show a large K SD adjustment.

- d. **Difference between right (OD) and left (OS) eyes:** if the difference for a parameter between OD and OS exceeds certain amount as recommended by the manufacturer (Appendix 2 & 3), for example, great than 0.3 mm for axial length difference, additional exams are required. This is true for both LenSTAR 900 (Haag-Streit) and IOLMaster (Zeiss). For average K power difference between two eyes, the criterion for LenSTAR 900 (Haag-Streit) and IOLMaster (Zeiss) is 1.25D and 0.90D respectively.
- 4. Topography and tomography are highly recommended in addition to routine biometry for refractive cataract surgeries.<sup>11</sup> In addition to the usage of helping to rule out OSD and confirming cornea stability after rigid contact lens wear as stated above, the corneal topography may reveal if the astigmatism is regular and may provide useful information for toric IOL selection. Topography and tomography can also help in confirming the presence of prior myopic or hyperopic corneal laser refractive surgery and IOL power calculation in those post-refractive surgical eyes.
- 5. Following and implementing the advancement in measurement technology. The newly developed IOLMaster 700 (Zeiss) and ARGOS (Alcon) utilize swept-source OCT technology increase the acquisition speed and can now measure AL in eyes with dense cataracts that previously would require immersion ultrasound.<sup>17, 18</sup>

### Conclusion

To achieve high post-operative refractive accuracy and patient satisfaction in cataract patients, it is critical to accurately detect OSD, retina/macular pathology and any other potential ocular diseases that may affect refractive and visual outcomes, and to avoid biometry measurement errors in order to make sure the input parameters in advanced IOL formulas are accurate.
